Posterior Shoulder Pain—Not Always a Muscle Spasm

Urgent message: Patients present to urgent care with a variety of complaints, many of which are common—even if they are the result of an uncommon condition. It is important that the provider develop a broad differential diagnosis as they approach these problems.

Case Presentation

History

A 52-year-old male presents to urgent care with the chief complaint of new lower posterior neck and right shoulder pain of 5 days' duration. He describes the pain as “aching.” It is aggravated by movement of his neck or shoulder. He feels that he may have “slept on it wrong.” There is no history of trauma. He denies headache, fever, numbness, or weakness in the right arm and neck. He is right hand dominant. His past medical history is significant for left nephrectomy for T1b Grade 2 renal cell carcinoma 9 years ago. He takes no chronic medications and has no known drug allergies.

Physical Examination

Physical exam reveals a slightly overweight male in no apparent distress. Vital signs:
- Blood pressure 156/98
- Pulse 90/min
- Respiratory Rate 16/min
- Temperature 97.9°F
- Weight 257 lbs
- Height 73 inches

The patient's head was normocephalic and atraumatic. He has tenderness in the right posterior neck and shoulder. He has pain with normal range of motion (NROM) of the neck (which was supple) and shoulders. He had normal upper extremity strength.

Follow-Up

The patient presented to the emergency department 3 days later after lack of response to methylprednisolone and cyclobenzaprine prescribed initially. Cervical spine x-rays demonstrated straightening of the cervical lordosis. He was discharged on oral medication. Three weeks later he presented to his primary care provider. Examination at that time was significant for Spurling's test with pain in the neck without radiation to the right arm. Radial pulses and temperature of hands were normal. He had 4/5 strength in the right biceps; otherwise no weakness was noted. He had an MRI of the cervical spine with mild spinal stenosis and mild broad-based disc herniation at C4-C5 and C5-C6. He was referred for elec-

Patients may start an imaging evaluation with plain cervical spine x-rays, shoulder x-ray, and possibly a chest x-ray to rule out a Pancoast tumor of the lung. MRI exams are obtained in the evaluation of these patients for not only the evaluation of the condition but also for exclusion of some of the conditions listed previously. With the advancement of MRI and ultrasound technology, structural peripheral nerve abnormalities called hourglass constrictions have been identified in some patients. Nerve conduction studies and EMG are essential in confirming PTS and excluding other causes. EMG findings may vary from mild to extensive denervation of the affected muscle group.

Treatment
Treatment in the acute phase of neuralgic amyotrophy involves adequate pain control. Pain can be severe and may require multimodal analgesia. Early corticosteroids may improve pain and speed up recovery. In patients that have failed conservative therapies, surgical options may be considered.

Conclusion
While cervical and shoulder pain are common complaints in urgent care, it is imperative to develop a broad differential diagnosis. As noted here, a common complaint was caused by an uncommon condition.

The patient experienced a fairly typical course for a patient with PTS. He presented with idiopathic pain and then progressed to weakness in his upper extremity. He made a full recovery; unfortunately, this is not the case for all patients. One large study showed 60% of patients still experienced pain 6 to 24 months in the clinical course and 80% had difficulty performing overhead tasks.
